

A SPECTROSCOPIC PERTURBATION ORIGIN FOR SULFUR MASS INDEPENDENT FRACTIONATION VIA THE B-X SYSTEM OF S₂

The Great Oxygenation Event (GOE), the introduction of O₂ into the Earth's atmosphere approximately 2.4 billion years ago, is a critical signpost in the development of life on Earth. The vanishing of sulfur isotope anomalies, called Sulfur Mass-Independent Fractionation (S-MIF), in the rock record is thought to be correlated with oxygenation of the early atmosphere. However, the mechanism for the generation of S-MIF in an anoxic atmosphere is unknown. Here, I propose a mechanism that involves spectroscopic perturbations in the B-X UV band system of S₂. This proposal is based on a global deperturbation analysis done by Green and Western^{a b} and work that I presented previously at this conference in 2015 (MG12) and 2016 (MG08). Specifically, perturbations of the "bright" B state by a "dark" B' state cause some isotopologues to have longer average excited state lifetimes than others. I demonstrate a difference between the shorter-lifetime symmetric (e.g. ³²S-³²S) isotopologues of S₂, for which nuclear permutation symmetry causes half of the rotational lines to be missing, and the longer-lifetime asymmetric isotopologues (e.g. ³³S-³²S). I also comment on general features of the B/B' system of S₂ that make it uniquely well-suited to generate a large MIF isotope effect.
